# The Viking Battle - Part 12015 Version: Icelandic 

Dæmi 1 Látum $n \geq 2$ vera heiltölu og látum $A_{n}$ vera mengið

$$
A_{n}=\left\{2^{n}-2^{k} \mid k \in \mathbb{Z}, 0 \leq k<n\right\} .
$$

Ákvarðið stærstu heiltölu $M_{n}$ sem ekki er hægt að rita sem summu einnar eða fleiri ekki nauðsynlega ólíkra staka úr $A_{n}$.

Dæmi 2 Skilgreinum fallið $f:(0,1) \rightarrow(0,1)$ með

$$
f(x)= \begin{cases}x+\frac{1}{2} & , x<\frac{1}{2} \\ x^{2} & , x \geq \frac{1}{2}\end{cases}
$$

Látum $a_{0}$ og $b_{0}$ vera tvær rauntölur pannig að $0<a_{0}<b_{0}<1$. Við skilgreinum runurnar $a_{n}$ og $b_{n}$ með $a_{n}=f\left(a_{n-1}\right)$ og $b_{n}=f\left(b_{n-1}\right)$ fyrir öll $n=1,2,3, \ldots$

Sýnið að til er jákvæð heiltal $n$ pannig að

$$
\left(a_{n}-a_{n-1}\right) \cdot\left(b_{n}-b_{n-1}\right)<0 .
$$

Dæmi 3 Látum $\Omega$ og $O$ vera umhring og ummiðju hvasshyrnds príhyrnings $A B C$ með $A B>B C$. Helmingalína hornins $\angle A B C$ sker $\Omega$ í $M \neq B$. Látum $\Gamma$ vera hring með pvermál $B M$. Helmingalínur hornanna $\angle A O B$ og $\angle B O C$ skera $\Gamma$ í punktunum $P$ og $Q$ í beirri röð. Punkturinn $R$ er valinn á línunni $P Q$ pannig að $B R=M R$. Sannið að $B R \| A C$. (Hér gerum við alltaf ráð fyrir að helmingalínur horna séu hálflínur.)

## Solution to problem 1

Answer: $M_{n}=(n-2) 2^{n}+1$.
Part 1. First we prove that every integer greater than $(n-2) 2^{n}+1$ can be represented as such a sum. This is achieved by induction on $n$.

For $n=2$, the set $A_{n}=\{2,3\}$. Every positive integer $m$ except 1 can be represented as a sum of elements of $A_{n}$ : as $m=2+2+\cdots+2$ if $m$ is even, and as $m=3+2+2+\cdots+2$ if $m$ is odd.

Now consider some $n>2$ and assume the induction hypothesis holds for $n-1$. Take an integer $m>(n-2) 2^{n}+1$. If $m$ is even, then

$$
\frac{m}{2}>(n-2) 2^{n-1}>((n-1)-2) 2^{n-1}+1
$$

Hence by the induction hypothesis

$$
\frac{m}{2}=\left(2^{n-1}-2^{k_{1}}\right)+\left(2^{n-1}-2^{k_{2}}\right)+\cdots+\left(2^{n-1}-2^{k_{r}}\right)
$$

for some $k_{i}$, with $0 \leq k_{i}<n-1$. It follows that

$$
m=\left(2^{n}-2^{k_{1}+1}\right)+\left(2^{n}-2^{k_{2}+1}\right)+\cdots+\left(2^{n}-2^{k_{r}+1}\right)
$$

giving us the desired representation as a sum of elements of $A_{n}$. If $m$ is odd, we consider

$$
\frac{m-\left(2^{n}-1\right)}{2}>\frac{(n-2) 2^{n}+1-\left(2^{n}-1\right)}{2}=(n-3) 2^{n-1}+1
$$

By the induction hypothesis there is a representation of the form

$$
\frac{m-\left(2^{n}-1\right)}{2}=\left(2^{n-1}-2^{k_{1}}\right)+\left(2^{n-1}-2^{k_{2}}\right)+\cdots+\left(2^{n-1}-2^{k_{r}}\right)
$$

for some $k_{i}$, with $0 \leq k_{i}<n-1$. It follows that

$$
m=\left(2^{n}-2^{k_{1}+1}\right)+\left(2^{n}-2^{k_{2}+1}\right)+\cdots+\left(2^{n}-2^{k_{r}+1}\right)+\left(2^{n}-1\right)
$$

giving us the desired representation of $m$ once again.
Part 2. It remains to prove that there is no representation of $M_{n}=(n-2) 2^{n}+1$. Let $N$ be the smallest positive integer that satisfies $N \equiv 1\left(\bmod 2^{n}\right)$, and which can be represented as a sum of elements of $A_{n}$. Consider the representation of $N$, i.e.

$$
N=\left(2^{n}-2^{k_{1}}\right)+\left(2^{n}-2^{k_{2}}\right)+\cdots+\left(2^{n}-2^{k_{r}}\right)
$$

where $0 \leq k_{1}, k_{2}, \ldots, k_{r}<n$. If $k_{i}=k_{j}=n-1$, then we can simply remove these two terms from the sum to get a representation for $N-2\left(2^{n}-2^{n-1}\right)=N-2^{n}$ as a sum
of elements of $A_{n}$, which contradicts our choice of $N$. If $k_{i}=k_{j}=k<n-1$, replace the two terms by $2^{n}-2^{k+1}$, which is also an element of $A_{n}$, to get a representation for $N-2\left(2^{n}-2^{k}\right)+2^{n}-2^{k+1}=N-2^{n}$. This is a contradiction once again. Therefor, all $k_{i}$ have to be distinct, which means that

$$
2^{k_{1}}+2^{k_{2}}+\cdots+2^{k_{r}} \leq 2^{0}+2^{1}+\cdots+2^{n-1}=2^{n}-1 .
$$

On the other hand
$2^{k_{1}}+2^{k_{2}}+\cdots+2^{k_{r}} \equiv-\left(\left(2^{n}-2^{k_{1}}\right)+\left(2^{n}-2^{k_{2}}\right)+\cdots+\left(2^{n}-2^{k_{r}}\right)\right)=-N \equiv-1 \quad\left(\bmod 2^{n}\right)$
Thus we must have $2^{k_{1}}+2^{k_{2}}+\cdots+2^{k_{r}}=2^{n}-1$, which is only possible if each element of $\{0,1,2, \ldots, n-1\}$ occurs as one of the $k_{i}$. This gives us

$$
N=n 2^{n}-\left(2^{0}+2^{1}+\cdots+2^{n-1}\right)=(n-1) 2^{n}+1
$$

In particular this means that $(n-2) 2^{n}+1$ cannot be represented as a sum of elements of $A_{n}$.

## Solution to problem 2

Note that

$$
\begin{array}{r}
f(x)-x=\frac{1}{2}>0 \text { if } x<\frac{1}{2} \\
f(x)-x=x^{2}-x<0 \text { if } x \geq \frac{1}{2} .
\end{array}
$$

We consider the interval $(0,1)$ divided into the two subintervals $I_{1}=\left(0, \frac{1}{2}\right)$ and $I_{2}=\left[\frac{1}{2}, 1\right)$. The inequality

$$
0>\left(a_{n}-a_{n-1}\right) \cdot\left(b_{n}-b_{n-1}\right)=\left(f\left(a_{n-1}\right)-a_{n-1}\right)\left(f\left(b_{n-1}-b_{n-1}\right)\right.
$$

holds if and only if $a_{n-1}$ and $b_{n-1}$ lie in distinct subintervals.
Let us now assume, to the contrary, that $a_{k}$ and $b_{k}$ always lie in the same subinterval. Consider the distance $d_{k}=\left|a_{k}-b_{k}\right|$. If both $a_{k}$ and $b_{k}$ lie in $I_{1}$, then

$$
d_{k+1}=\left|a_{k+1}-b_{k+1}\right|=\left|a_{k}+\frac{1}{2}-\left(b_{k}+\frac{1}{2}\right)\right|=d_{k} .
$$

If, on the other hand, $a_{k}$ and $b_{k}$ both lie in $I_{2}$, then $a_{k}+b_{k} \geq \frac{1}{2}+\frac{1}{2}+d_{k}=1+d_{k}$, which implies

$$
d_{k+1}=\left|a_{k+1}-b_{k+1}\right|=\left|a_{k}^{2}-b_{k}^{2}\right|=\left|\left(a_{k}-b_{k}\right)\left(a_{k}+b_{k}\right)\right| \geq d_{k}\left(1+d_{k}\right)
$$

This means that the difference $d_{k}$ is non-decreasing, and particular $d_{k} \geq d_{0}>0$ for all $k$.

If $a_{k}$ and $b_{k}$ lie in $I_{2}$, then

$$
d_{k+2} \geq d_{k+1} \geq d_{k}\left(1+d_{k}\right) \geq d_{k}\left(1+d_{0}\right)
$$

If $a_{k}$ and $b_{k}$ lie in $I_{1}$, then $a_{k+1}$ and $b_{k+1}$ both lie in $I_{2}$, and so we have

$$
d_{k+2} \geq d_{k+1}\left(1+d_{k+1}\right) \geq d_{k+1}\left(1+d_{0}\right) \geq d_{k}\left(1+d_{0}\right)
$$

In either case, $d_{k+2} \geq d_{k}\left(1+d_{0}\right)$, and inductively we get

$$
d_{2 m} \geq d_{0}\left(1+d_{0}\right)^{m}
$$

For sufficiently large $m$, the right-hand side is greater than 1 , a contradiction. Thus there must be a positive integer $n$ such that $a_{n-1}$ and $b_{n-1}$ do not lie in the same subinterval, which proves the desired statement.

## Solution to problem 3

Let $K$ be the midpoint of $B C$, i.e. the centre of $\Gamma$. Notice that $A B \neq B C$ implies that $K \neq O$. Clearly the lines $O M$ and $O K$ are perpendicular bisectors of $A C$ and $B M$, respectively. Therefore, $R$ is the intersection point of $P Q$ and $O K$.

Let $N$ be the second point of intersection of $\Gamma$ with the line $O M$. Hence $B N \|$ $A C$, and it suffices to prove that $B N$ passes trough $R$. Our plan for doing this is to interpret the lines $B N, O K$ and $P Q$ as the radical axes of three appropriate circles.

Let $\omega$ be the circle with diameter $B O$. Since $\angle B N O=\angle B K O=90^{\circ}$, the points $N$ and $K$ lie on $\omega$.

Next we show that the points $O, K, P$, and $Q$ are concyclic. To this end, let $D$ and $E$ be the midpoints of $B C$ and $A B$, respectively. By our assumption of triangle $A B C$, the points $B, E, O, K$, and $D$ lie on $\omega$ is this order. It follows that $\angle E O R=\angle E B K=\angle K B D=\angle K O D$, so the line $K O$ externally bisects the angle $P O Q$. Since the point $K$ is the centre of $\Gamma$, it also lies on the perpendicular bisector of $P Q$. So $K$ coincides with the midpoint of the arc $P O Q$ of the circumcircle $\gamma$ of triangle $P O Q$.

Thus the lines $O K, B N$, and $P Q$ are pairwise radical axis of the circles $\omega, \gamma$ and $\Gamma$. Hence they are concurrent at $R$, as required.
